"TGF β 1-INHIBITOR PEPTIDES"

DESCRIPTION OF THE STATE OF THE ART

5 Cell growth is regulated by various proteins of the growth factor group (Schalch DS et al. (1979) Endocrinology 104:1143-1151). The most important growth factors involved in cell development, and able to act by autocrine and paracrine mechanisms, include the transforming growth factors (TGFs) (Braun L. et al. (1988) Cell Biol. 85:1539-1543; Lyons RM and Moses HL (1990) Eur. J. Biochem. 187:467-473).

The term TGF was first used for describing the activity produced by a cell line transformed with the murine sarcoma virus (deLarco JE and Todaro GJ (1978) Proc. Natl. Acad. Sci. 75:4001-4005; Mizel SB et al. (1980)Proc. Natl. Acad. Sci. 77:2205-2208). supernatant of these cells was able to induce normal growth, in soft agar, of cells that require a solid support for growth. More specific studies demonstrated two classes of TGF, called TGF α and TGF β , which in turn comprise families of related proteins. The $TGF\beta$ family consists of 5 isoforms (Brand T. and Schneider (1995) J. Mol. Cell Cardiol. 27:5-18) of dimeric structure (Schlunneger MP and Grutter MG (1992) Nature 358:430-434; Brand T. and Schneider MD (1995) J. Mol. Cell Cardiol. 27:5-18). Investigations of the mature proteins, purified from a single species, demonstrated a high degree of identity between their sequences (Table 1).

Table 1. Homology among different types of TGF β s. TGF β 1, TGF β 2 and TGF β 3 derived from humans, TGF β 4 derived from chicken and TGF β 5 from frog. (Roberts AB and Sporn MB, 1990).

10

15

% of	TGFβ1	TGF β 2	TGFβ3	TGFβ4	TGFβ5
TGFβ1	100				-
TGFβ2	71	100			
TGF β 3	72	76	100		
TGFβ4	82	64	71	100	
TGFβ5	76	66	69	72	100

TGF β 1 is synthesized as a precursor of 390 amino acids called Pre-Pro-TGF β 1. In a first hydrolysis there is release of a hydrophobic fragment of 29 amino acids, which gives rise to Pro-TGF β 1. Then the mature TGF β 1 is released by another cut in a region that precedes the terminal amino of TGF β 1 and that consists of two arginines, giving rise to a protein of 112 amino acids with a molecular weight of 12 kDa. To produce the biologically active form, two of these monomers join together by means of disulphide bridges, yielding a dimer of 25 kDa. Alterations of this structure cause loss of biological function (Barnard JA et al. (1990) Biochim. Biophys. Acta 1032:79-87).

Various domains are known to exist within the structure of TGF β 1. One of these domains is found to be located between amino acids 40 and 82 and is involved in the binding of TGF β 1 to its cell receptors (Quian SW et al. (1992) Proc. Natl. Acad. Sci. 89:6290-6294; Burmester JK et al. (1993) Proc. Natl. Acad. Sci. 90:8628-8632).

Receptors of TGF β 1 and other binding proteins

25

30

20

• Five types of specific receptors for TGF β 1 have been characterized (Cheifetz S et al. (1988) J. Biol. Chem. 263:17225-17228 and López Casillas F. et al. (1991) Cell 67:785-795). These receptors have different affinities for the different types of TGF β 1. Receptors

15

20

25

of type I, II and III are the best understood so far (reviewed in Attisano L et al. (1994) Biochim. Biophys. Acta 1222:71-80; Derynck R. (1994) Trends Biochem. Sci. 19:548-553; Yingling et al. (1995) Biochim. Biophys. Acta 1242:115-136). Type IV receptors have also been described (MacKay K. and Danielpour D. (1991) J. Siol. 266:9907-9911) and type V (Ichijo H. et al. (1991) J. Biol. Chem. 266:22459-22464). It has also been reported that the transmembrane and cytoplasmic domains of endoglin (Cheifetz S at al. (1993) J. Biol. Chem. 267:19027-19030; Bellón T. et al. (1993) Eur. J. Immunol. 23:2340-2345; Yamashita et al. (1995) J. Biol. Chem. 269:1995-2001; Zhang H. et al. (1996) J. Immunol. 156:564-573)) have approximately 70% similarity with the type III receptors, both human and of the rat.

RIII would be the one with the task of binding TGF\$1 and presenting it to RII which in its turn would form a complex with RI (Yamashita et al. (1994) J. Biol. Chem. 269:20172-20178) or to complexes in which various molecules of RI are combined with RII (Weiss G. (1996) EMBO J 15:276-289). and Massagué J. interaction would give rise to phosphorylation of RI serine/threonine activation of its subsequent kinase which would phosphorylate to second messengers like the MADR2 proteins (Macias-Silva M et al., (1996) Cell 87:1215-1224).

(1)

differentiation and of TGF\$1 in hepatic Role regeneration

30

35

The effects produced are different depending on the moment of development and on the type of cell.

· Enlargement of the extracellular matrix, on acting upon the liver stellate cells (Ito cells), the principal source of matrix proteins (Mustce TA et al. (1987) Science 237:1333-1336).

REPLACEMENT SHEET

10

- Differentiation of the epithelial cells and hepatocytes (Florini JR et al. (1986) J. Biol. Chem. 261:16509-16513).
- Inhibition of cell growth during the process of liver regeneration. This effect is of great importance in the maintenance of cell rest *in vivo* (Kato Y et al. (1988) Proc. Natl. Acad. Sci. 85:9552-9556).
 - Inhibition of endocytosis of the receptor of the epithelial growth factor (EGF) as has been observed in cultures of foetal rat hepatocytes (Noda M. and Rodan GA (1987) J. Cell Physiol. 133:426-437).

Role of $TGF\beta 1$ in hepatic fibrosis

15 $TGF\beta 1$ has been found to be associated with the processes of hepatic fibrosis (Czaja MJ et al. (1989) J. Cell Biol. 108:2477-2482; Annoni G. et al. (1992) J. Hepatol. 14:259-264) causing an increase in production of proteins of the extracellular matrix, by the liver 20 stellate cells (lipocytes or Ito cells), of receptors and inhibiting synthesis of the proteolytic enzymes that degrade the matrix (Ignotz RA and Massagué J. (1986) J. Biol. Chem. 261:4337-4345). In the liver, $TGF\beta 1$ induces the synthesis of collagen and fibronectin 25 in the liver stellate cells (Weiner FR Hepatology 11:111-117). There is also auto-regulation by increasing its own synthesis, via induction of its mRNA.

TGFB1 has also been found to be involved 30 increased synthesis of $\alpha 2\text{-macroglobulin}$ synthesized by the hepatocytes and the activated liver stellate cells. By binding to TGFB1 and causing its inactivation (Bachem MG (1994) Ann NY Acad. Sci. 737:421-424), α 2macroglobulin is said to eliminate $TGF\beta1$ from 35 extracellular compartments.

10

20

- 5 -

Investigation of patients with chronic liver damage has shown that there is a correlation between expression of $TGF\beta 1$ and expression of the mRNA for the type I procollagen and the serum levels of type III peptide of procollagen (Castilla A. et al. (1991) N. Engl. J. Med. 324:933-940).

Patients with cirrhosis of the liver have a shorter than normal life expectancy owing to the complications that arise in the course of the disease, such as portal hypertension or hepatic failure.

Effect of TGF β 1 on the extracellular matrix

Interaction of $TGF\beta 1$ with the cell receptors 15 causes:

- Activation of synthesis of procollagen, fibronectin (Ignotz RA et al. (1987) J. Biol. Chem. 262:6443-6446) and related proteins, including membrane proteins capable of interacting with the components of the extracellular matrix (Carter WG (1982) J. Biol. Chem. 257:13805-13815).
- Inhibition of the synthesis of proteolytic enzymes capable of degrading the matrix (Fukamizu H. and Grinnell F. (1990) Exp. Cell Res. 190:276-282).
- Stimulation of the synthesis of inhibitors of proteolytic enzymes (Fukamizu H. and Grinnell F. (1990) Exp. Cell Res. 190:276-282).

These effects lead to an increase in interactions ofcell with the extracellular matrix, combined with greater reorganization of the proteins of 30 which it is composed, gives rise to an increase in the total quantity of extracellular matrix (Roberts CJ et al. (1988)J. Biol. Chem. 263:4586-4592). findings confirm that TGFβ1 is involved in 35 cicatrization processes (Fukamizu H. and Grinnell F.

- 6 - (1990) Exp. Cell Res. 190:276-282; Barnard JA et al. (1990) Biochim. Biophys. Acta 1032:79-87).

Peptides as inhibitors of ligand-receptor interaction

5

10

15

20

25

30

There is the possibility of using small molecules, synthetic peptides, as analogues of molecules that are present in the body, with the aim of emulating their function. Studies conducted by LeSateur demonstrate the possibility of using cyclized analogues of nerve growth factor (NGF), emulating the β turn region, permitting its binding to the receptor al. (LeSateur L. et (1996)Nature Biotechnology 14:1120-1122). It is also possible to use peptides as antagonists of these molecules, preventing the native interacting with its receptor by blocking mediated by the peptide (Lasarte JJ et al. (1994) J. Acquired Immune Deficiency Syndromes 7:129-134: LeSateur et al. (1995) J. Biol. Chem. 270:6564-6569). Earlier studies had demonstrated the usefulness of synthetic peptides as inhibitors of ligand-receptor interaction even when the recognition epitope is not continuous (Daniels AJ et al. (1995) Mol. Pharmacol. 48:425-432). Other studies conducted with the type II receptor of $TGF\beta1$ and with fetuin, a glycoprotein in the group of type II receptors, have demonstrated the possibility of using cyclized peptides as inhibitors of the interaction of $TGF\beta1$ with RII (Demetriou M. et al. (1996)J. Biol. 271:12755-12761). Chem. With this cyclization it becomes possible to obtain peptides with a structure similar to that which could be obtained in vivo.

DETAILED DESCRIPTION OF THE INVENTION

For the reasons stated above, we consider that peptides derived both from $TGF\beta 1$ and from its receptors, or from proteins with capacity for binding to $TGF\beta 1$, could be inhibitors of the action of $TGF\beta 1$. We therefore decided to explore this possibility.

10 Selection of the peptides to be synthesized

The peptides for synthesis were selected in different ways depending on whether they were derived from $TGF\beta 1$ or from its receptors.

In the case of the sequence of $TGF\beta 1$, peptides were synthesized from 15 amino acids that include the whole sequence of $TGF\beta 1$. Each peptide had 10 amino acids in common with its two immediate neighbours.

In the case of the sequences of its receptors, the peptides were chosen on the basis of software designed in our laboratory. One of the computer programs compares two amino acid sequences, with the aim of predicting partially complementary regions. Other programs were also used that were able to predict the regions of the proteins that would be most exposed, on the basis of the hydrophobicity and hydrophilicity of the amino acids making up their sequence.

Synthesis of peptides

30

35

20

25

5

The peptides were synthesized by the solid phase method (Merrifield (1963) J. Am. Chem. Soc. 85: 2149-54), using fluorenylmethyloxycarbonyl (Fmoc) as a temporary protecting group of the alpha-amino group (Atherton et al. (1989) Journal of Chemical Society Perkins Transactions 1: 538-546). For the synthesis of

small quantities of a large number of peptides, a multiple synthesizer was used, permitting the simultaneous synthesis of 96 peptides (Borrás-Cuesta et al. (1991) Biologicals 19: 187-190). The peptides were stored at -80°C in the solid state until used.

Purification of the peptides by HPLC

The synthesized peptides were analysed and 10 purified by high-performance liquid chromatography (HPLC), using a Waters 600E-900 system (Millipore Corp., Bedford, USA).

A Waters Radial-Pak^m C_{18} 300 Å 15 μ m, 8x100mm column (Millipore Corp., Bedford, USA) was used for 15 analysis of the peptides by analytical HPLC. peptide was dissolved in a 0.1% solution of TFA in distilled water, to a maximum concentration of 1 mg/ml. The solution of peptide was injected (100 μ l) into the column and was eluted in a water/acetonitrile gradient 20 (Fig. 15) (Romil Ltd., Cambridge, USA) both with 0.1% TFA at a flow rate of 1 ml/min. The fractions that contained the peptide were detected by its absorbance at 220 nm and 280 nm (photodiode array detector, Waters 991, Millipore Corp., Bedford, USA).

A Waters Delta-Pak^m C₁₈ 300 Å 15 μm, 25x100mm column (*Millipore Corp.*, *Bedford*, *USA*) was used for its purification. The peptide was dissolved and was injected (2 ml) under the same conditions as in the preceding case, employing the same gradient at a flow rate of 5 ml/min. The fraction that contained the pure peptide was collected in a flask.

IN VITRO TESTS. INVESTIGATION OF THE ACTIVITY OF THE PEPTIDES

5 Cell lines

A line derived from mink pulmonary epithelium, MV-1-Lu, was used (CCL-64, American Type Cell Culture, Virginia, USA). The cells were grown in 162 cm2 culture flasks (Costar Corporation, Cambridge, USA) in a stove 10 at 37°C and 5% CO_2 , until subconfluence was attained. A complete medium was used: RPMI 1640 with L-glutamine (GibcoBRL, Life Technologies Ltd., Paisley, Scotland) supplemented with 5% of foetal calf serum Biological Industries, Kibbutz Beit Haemek, Israel), 10 15 (1M HEPES Buffer, Bio-Whittaker, Verviers, mM HEPES Belgium) and antibiotics (100 U/ml penicillin and 100 μ g/ml streptomycin).

20 Test of inhibition of the growth of the MV-1-Lu cell line

The MV-1-Lu cells grown as indicated above were removed from the bottom of the culture flasks using 5 ml of trypsin-EDTA (Biological Industries, Kibbutz 25 Beit Haemek, Israel), resuspended in complete medium and centrifuged at 1500 rev/min for 8 minutes. After centrifugation the cells were resuspended in complete medium to a concentration of 50,000 cells/ml. conducting the test, 10 ml of the cell suspension were 30 taken and dispensed in 96-well, flat-bottom culture plates (Costar Corporation, Cambridge, USA), adding 100 μ l/well, and were incubated overnight at 37°C and 5% CO_2 , which permits adhesion of the cells to the 35 bottom of the wells. At the end of this time, peptides to be tested were added in RPMI, to a final

concentration of μ g/ml in the presence of 200 concentration of 200 pg/ml of TGF β 1 in RPMI Systems Europe Ltd., Abingdon, UK) . The concentration of FCS in the well was 2.5%. After 24 hours of incubation, 1 μ Ci of tritiated thymidine was added per well (25 Ci/mmol [methyl- ^{3}H]-thymidine, Amersham LifeScience, Buckinghamshire, incubation for a further 12 hours (Grubeck-Loebenstein B. et al. (1989) J. Clin. Invest. 83:764-770; Brennan 10 FM et al. (1990) Clin. Exp. Immunol. 81:278-285).

At the end of the incubation periods the cells were removed from the bottom of the wells with trypsin-EDTA and were collected using a manual harvester (Titertek cell harvester, Skatron Instruments Inc., 15 Sterling, USA) which ruptures the cells, collecting the in nitrocellulose filters (Filter MAT 11731, Skatron Instruments Inc., Sterling, USA) where it is fixed. The filters were placed individually in 5 ml polypropylene tubes to which 4 ml of scintillation 20 fluid was added (Biogreen-11, Reactivos Scharlau S.A., Barcelona, Spain). The activity of each tube quantified for 90 seconds in a β LKB scintillation counter (Beta plate system, LKB, Uppsala, Sweden).

- Investigation of inhibition of binding of TGFβ1 to the cell receptors

 Selective labelling of the cell receptors (affinity labelling)
- The MV-1-Lu cells were removed from the culture flasks incubating them at 37°C for 10 minutes, with 10 ml of solution 1 (128 mM NaCl, 5 mM KCl, 25 mM 4-(2-hydroxyethyl)-1-piperazine ethanesulphonate at pH 7.5, 5 mM glucose and 1 mM EDTA). The cells thus removed were resuspended in solution 2 (128 Mm NaCl, 5 mM KCl, 50 mM 4-(2-hydroxyethyl)-1-piperazine ethanesulphonate

at pH 7.5, 1.2 mM $CaCl_2$, 1.2 mM $MgSO_4$ and 5 mg/ml BSA) and were collected by centrifugation at 1000 x g for 5 minutes. After centrifugation the cells were resuspended in solution 2 at a concentration of 10^6 cells/ml.

From this cell suspension, 0.5 ml aliquots were made in 24-well plates (Greiner GmbH, Frickenhausen, Germany), the peptides were added, in 50 µl of a 0.8 mg/ml solution, then this was incubated for 2 hours at 4°C with stirring. Next, 125 I-TGFβ1 (2µCi) was added to a final concentration of 277.2 pM (125 I-TGFβ1 human recombinant 800-2200Ci/mmol, Amersham Life Science, Buckinghamshire, UK) and this was incubated for a further two hours at 4°C with stirring.

15 After incubation, the cells were transferred to a centrifuge tube and were centrifuged cold at 12,000 x gfor 1 minute. They were then washed twice in cold solution 2 and were resuspended in 0.5 ml solution 2, 5 μ l of dimethyl sulphoxide (DMSO 99.5%, Sigma Chemical Co., St. Louis, USA) and disuccimidyl 20 suberate (DSS, Pierce Chemical Co., Rockford, giving a final concentration of 0.25 mM of DSS. Reaction was stopped at 15 minutes by dilution, centrifugation and washing with a solution containing 25 0.25M saccharose, 10 mM Tris and 1 mM EDTA at pH 7.4. The precipitate of cells was resuspended in 0.5 ml of Triton X-100 (Bio-Rad Laboratories, Hercules, USA) v/v, 10 mΜ Tris at pH 7.0, 1 mΜ EDTA, phenylmethylsulphonyl fluoride, 1 µg/ml pepstatin and 30 1 μg/ml leupeptin (Sigma Chemical Co., St. Louis, USA) and incubated for 40 minutes at 4°C. The fraction that is insoluble in detergent is separated by centrifugation at $12,000 \times g$ for 15 minutes. fractions that are soluble in detergent (supernatant) 35 insoluble (precipitate) were frozen and at

(Massagué J. and Like B. (1985) J. Biol. Chem. 260:2636-2645).

Electrophoresis of proteins in sodium polyacrylamide dodecyl sulphate gel

The fractions soluble and insoluble in detergent were used for analysis by electrophoresis in acrylamide/bisacrylamide gels at 7.5% for 5-6 hours at 220 volts.

The proteins were stained with a solution of (comassie brillant blue® R250 (Serva Feinbiochemica GmbH, Heidelberg, Germany) in methanol (50%), acetic acid (10%) and distilled water, for 30 minutes.

Subsequent washings were effected with a solution of methanol (50%), acetic acid (10%) and distilled water for 15 minutes, in the first washing, and methanol (2.5%), acetic acid (0.5%) and distilled water, in the subsequent washings, until the background colour was removed.

Flow cytometry

Inhibition of the binding of $TGF\beta1$, mediated by peptides, to the cell receptors was measured by the 25 direct immunofluorescence method. An immunofluorescence kit was used for this (Fluorokine rh TGF β -biotin, R&D Systems Europe Ltd., Abingdon, UK). This test is based on the capacity of biotinylated $TGF\beta 1$ to bind to the 30 cell receptors, in a specific manner, and the subsequent interaction of the biotin with fluoresceinlabelled avidin, so that the signal intensity will depend on the quantity of TGF β 1 bound to the cell receptors.

The MV-1-Lu cells grown in 162 cm² flasks were removed using solution 1 (described previously) and

15

were resuspended in physiological saline for centrifugation at $500 \times g$ for 5 minutes. After centrifugation, the cells were resuspended again physiological saline at a concentration of $4 \times 10^6 \text{ cells/ml}$. 25 μl of the cell suspension was added to 12x75 mm borosilicate tubes, to which was added the peptide to be tested in 40 μ l of RPMI 1640 medium, giving a final concentration of 0.42 μ g/ μ l and 10 μ l of biotinylated $TGF\beta 1$. As a control of specificity, 10 ul of a biotinylated reagent supplied with the kit was added, 10 μ l of biotinylated TGF β 1 was added as a positive control and 20 μ l of anti-TGF β 1 blocking antibody was added as a negative control. Physiological saline was added to all the controls until a total volume of 75 μ l was reached. All the tubes incubated for 1 hour at 4°C in darkness.

At the end of the incubation period, 10 μ l of fluorescein-labelled avidin was added, incubating for 30 minutes at 4°C in darkness, after which 2 ml of a 20 washing solution (RDF1) was added, followed centrifugation at $500 \times g$ for 6 minutes. The cell precipitate was resuspended in 0.2 ml of cold PBS for cytometry (FACScan, Becton Dickinson Immunocytometry Systems, California, USA). This method permits 25 measurement of the fluorescence emitted by each cell when a laser beam is incident upon it, by means of a computer program $(Lisys^{TM})$ II, Becton Dickinson Immunocytometry Systems, California, USA). Fig. 16 shows a typical image from analysis by flow cytometry.

To obtain the data on inhibition of the binding of $TGF\beta 1$ to the receptors, the positive control of the test was used for delimiting the fields corresponding to the labelled cells, that have bound to the $TGF\beta 1$ -biotin (M2) and to the unlabelled cells (M1). Once the fields had been delimited, the percentage of cells

located in each of them was calculated. The same was done with the data obtained when the peptide incubated with TGF\$1-biotin the or with cells, whether they depending on were derived from the receptors or the $TGF\beta1$ respectively. With these data, percentage inhibition of each peptide was calculated using the following formula: 100 -((M2 Peptide-M2 Negative) х 100 / (M2 Positive-M2 Negative)).

5

EXPERIMENTS IN VIVO. EXPERIMENTAL MODEL OF FIBROSIS

Male white rats (albino Wistar strain) from simultaneous litters (5 weeks ± 1.5 weeks) were used, in order to obtain a group that was homogeneous in age and initial weight. Throughout the experiments, the animals were kept in conditions of constant temperature (22°C) with a 12-hour cycle of light and darkness. They had free access to water and food.

20 Hepatic cirrhosis (HC) was induced by inhalation of carbon tetrachloride for 11 weeks, twice per week (López Novoa JM et al. (1976) Patología IX:223-240; Camps J. et al. (1987) Gastroenterology 93:498-505). Exposure to CCl₄ was effected by bubbling compressed air, at a flow rate of 3 litres/min, through a gas 25 wash-bottle. One minute of exposure was used initially, increasing by one minute per week until 4 minutes was reached in the fourth week. CCl4 was not administered during the fifth week, starting again at the sixth week. 30 with an exposure of 5 minutes. This exposure time was maintained until week 11. 400 mg/l of phenobarbital (Luminal®, Bayer, Leverkusen, Germany) was added to the drinking water, from one week before starting exposure to CCl_4 and until the end of the experimental period. Before starting the treatment, one week was left, in 35 which they were not administered CCl4. During treatment

they were administered a weekly dose of CCl_4 , as recorded (Fig. 2).

Distribution of the animals

5

The animals were divided into 4 groups before beginning the process of induction of hepatic cirrhosis.

10 Healthy controls (Co): Animals that were not subjected to the fibrosis process.

Treated healthy controls (Co+P144): Animals that were not subjected to the fibrosis process and that were administered the peptide P144 during the last 3 weeks (coinciding in time with the treatment of the group of rats Tto₂).

Cirrhotic controls 1 (Ci_1): Animals subjected to the 20 process of induction of cirrhosis by inhalation of CCl_4 twice per week. These animals were separated into 2 groups on reaching the fifth week:

Cirrhotic controls 1 (Ci₁): Animals that continued to be subjected to the process of induction of fibrosis up to week 11, without being administered the peptide P144. They were administered saline serum on alternate days, throughout the induction process (weeks 5 to 11).

30

Treated cirrhotics 1 (Tto₁): Animals that were administered the peptide P144 derived from the sequence of the type III receptor, on alternate days, during the process of induction of fibrosis, from week 5 to week 11.

35

10

15

Cirrhotic controls 2 (Ci_2) : Animals that continued to be subjected to the process of induction of fibrosis without receiving the peptide P144 or saline serum. This group was subdivided into another two on reaching week 11.

<u>Cirrhotic controls 2</u> (Ci_2): Cirrhotic animals that were not subjected to any type of treatment, kept as controls. These animals received injections of saline serum for 3 weeks (weeks 13 to 15).

Treated cirrhotics 2 (Tto_2): Cirrhotic animals that were treated with the peptide derived from the sequence of the type III receptor (P144), for 3 weeks (weeks 13 to 15).

Treatment of the animals

- Group Tto1: These animals underwent treatment during the fibrosis process. Treatment with the peptide started in the fifth week (before exposure to CCl4 for 5 minutes) and continued up to the end of the eleven weeks of the cirrhosis induction process.
- Group Tto₂: These animals underwent treatment after completion of the process of induction of cirrhosis (11 weeks). Treatment started one week after the last inhalation of CCl₄ and continued for 21 days.

Before starting the treatment and on its completion, blood was taken from all the animals that had been treated with the peptide. The peptide was administered by subcutaneous injection in the abdominal dose of 70 μg/animal in 500 μl physiological saline.

25

Sacrifice of the animals and dissection of the liver

On completion of treatment of the animals with the peptide, both in the model with rats and in that with mice, the animals were sacrificed by decapitation, after taking blood from them from the retro-orbital plexus with a capillary.

This was followed immediately by dissection of the liver and collection of samples.

The samples were cut and placed in formol as fixing solution, for later histologic examination. Other fragments were placed in cryotubes, which were immersed in liquid nitrogen and then stored at -80°C.

15 Anatomopathologic evaluation of the liver

Histologic examination was carried out on fragments of liver previously fixed in formol for at least 24 hours, after which they were placed in ethanol (70%).

After dehydrating they were embedded in paraffin blocks. Successive sections 3 µm thick were prepared from the blocks obtained, using a Leitz and steel blades. Prior to staining microtome sections were deparaffined in xylene (AnalaR, Poole, UK) for 15 minutes, after heating them at 60°C in a stove for 15 minutes, and they were hydrated by successive passes through alcohols of decreasing concentration 100%, 96%, 80% and 70% and finally in

30 water. The following stains were used:

Haematoxylin-eosin.

Masson's trichromic (Locquin M. and Langeron, (1985) in Manual de Microscopía Ed. Labor S.A. Barcelona): Uses a specific dye for collagen proteins (green light).

35 Sirius Red: A stain specific for collagen.

- 18 -

Confirmation of hepatic fibrosis: image analysis

image analysis of the samples obtained, light microscope was used (Olympus BH-2, Tokyo, Japan) connected to a video camera (Sony DXP-950P, Sony Co., Tokyo, Japan), with which the various fields of each preparation were photographed. Six fields were taken at random from each preparation stained with Sirius Red. The various images captured were analysed by means of a computer program (Visilog 4.1.5, Noesis, Orsay, France) which calculates the area of fibrosis and the total area of the preparation. From these data, a fibrosis index (area of fibrosis/total area) was calculated for each field. To be able to use this program it was necessary to modify image acquisition by polarized light filters (Olympus U-POT, Tokyo, Japan) and green light filters (Olympus IF550, Tokyo, Japan) which made it possible to automate the process of sample analysis.

Detection of collagen in 14 μm sections of paraffintreated tissue

The 14 μm sections that were used for this 25 technique were obtained in the same way as the 3 μm sections mentioned previously. These sections subjected to a process of deparaffination for 12 hours in xylene. Once the paraffin had been eliminated, the samples were hydrated by passing them through different grades of alcohol 96%, 80%, 50%, completing the process 30 in distilled water.

Once hydrated, they were subjected to a process of prestaining in a solution of 160 mg of Fast Green FCF (Fluka Chemika-BioChemika, Buchs, Switzerland) in 160 ml of saturated picric acid (Merck, Darmstadt, Germany) for 15 minutes in darkness. The samples were

washed by immersion in water until they no longer coloured the wash water. Once the surplus dye was removed, the samples were stained for 30 minutes in darkness in a solution of 160 mg of Direct Red 80 (Fluka Chemika-BioChemika Buchs, Switzerland) and 64 mg of Fast Green, both dyes in 160 ml of saturated picric acid. They were washed again until the surplus dye was removed, and then the samples were removed from the slides by scraping the sample off with a small spatula.

The sections removed in this way were placed in separate tubes containing 3 ml of a solution of NaOH 0.1 N (Quimón, Montplet&Esteban S.A., Barcelona, Spain) and methanol (1:1). Aliquots were taken from the various tubes for reading in the spectrophotometer

15 2 (Lambda *UV/VIS* spectrophotometer, Perkin-Elmer, Norwalk, USA) at wavelengths of 540 nm and 630 nm using as blank an aliquot of the solution of NaOH 0.1 N and methanol (López de León Α. and Rojkind (1985) Histochem. Cytochem. 33:737-743; Gaudio E. et al.

20 (1993) Int. J. Exp. Path. 74:463-469).

In accordance with the works of Gaudio E. et al. (1993) Int. J. Exp. Path. 74:463-469), the following formulae were used for finding the quantities of collagen and total protein:

25

30

5

mg collagen = $\underline{\text{absorbance at 540 nm}}$ - $\underline{\text{absorbance at 630 nm}}$

mg collagen/mg total protein = mg collagen

mg collagen + mg non-collagen proteins

Non-collagen proteins = $\underline{absorbance at 630 nm}$

Statistical analysis of the results

The data obtained in the experiments in vivo were subjected to statistical analysis. Normality of the

quantitative variables was verified by the Shapiro-Wilks test.

As the data had not been adjusted to a normal distribution, non-parametric statistical analysis was undertaken. Comparison between groups was effected by means of Kruskal-Wallis H followed by comparison of Mann-Whitney U. The data were presented graphically by means of boxes, with representation of the median of the data (thick line inside each box), together with the interquartile range (height of the box), whereas the "whiskers" of each box represent the highest and lowest observations within a given interquartile range.

The association between variables was investigated using Fisher's exact test. Logistic regression was employed for investigating the independence of association of these variables.

A value of P equal to or less than $0.05~{\rm was}$ regarded as significant.

All the statistical analyses were accomplished 20 using the program SPSS for Windows V 6.1.3.

INHIBITION IN VITRO OF THE ACTIVITY OF TGFβ1

Test of inhibition of cell growth of the MV-1-Lu line

25

10

15

TGF β 1 is a cytokine that is able to inhibit the growth in vitro of the MV-1-Lu cell line (Grubeck-Loebenstein B. et al. (1989) J. Clin. Invest. 83:764-770; Brennan FM et al. (1990) Clin. Exp. Immunol. 81:278-285), therefore this line was used for testing 30 blocking effect of peptides on TGFB1. different combinations of media, cells and thymidine, we studied the effect of different concentrations of on incorporation of $[methyl-^3H]$ thymidine MV-1-Lu cells in culture, for determining the most 35

suitable conditions for the test. These conditions are shown in Fig. 3.

Once both the optimum concentration of MV-1-Lu cells (5000 cells/well) and the lowest concentration of TGF β 1 capable of producing inhibition of about 90% (200 pg/ml, Fig. 18) had been determined, the inhibitory effect of the synthetic peptides at a concentration of 200 μ g/ml was tested.

10

25

30

5

Inhibition in vitro of the activity of TGF β 1 by synthetic peptides

The synthetic peptides that are potentially 15 inhibitors of $TGF\beta1$ activity, selected as indicated above in the section: selection of the peptides to be synthesized (both those derived from proteins that bind TGFB1 and $TGF\beta1$ itself) were tested using the MV-1-Lu cell line. The peptides were dissolved in buffered RPMI medium, free from foetal calf serum, and 20 the following procedure was used:

The peptides belonging to the sequence of the receptor, or complementary to the peaks of hydrophilicity of TGF\$1, were incubated for 30 minutes in the presence of this cytokine and were then combined with the cell culture. The peptides derived from the sequence of $TGF\beta 1$ were added to the cell culture prior to addition of $TGF\beta1$, since they interact with the receptors of the cell surface. These incubations were effected in 100 μl of the same medium as was used for adding the cells. The active peptides permitted cell growth to a greater or lesser degree depending on its ability to inhibit TGF\$1.

Inhibition of TGF β 1 by means of peptides derived from TGF β 1

In a first stage, overlapping peptides derived from $TGF\beta 1$ were synthesized. These peptides (Table 2) were synthesized in the hope that some of them could bind to the cell receptors, thus preventing the binding of natural $TGF\beta 1$ to these receptors.

Table 2. Peptides derived from $TGF\beta1$. The number of the peptide is shown, together with its position in the complete sequence, as well as its amino acid sequence. For convenience of synthesis, all the peptides were synthesized with an alanine added at the C-terminal end which is not shown in the table.

5 Fig. 4 shows the inhibitory effect of the peptides Table 6 on the activity of $TGF\beta1$. Since inhibits growth of the MV-1-Lu cells, inhibition of this cytokine by the peptides leads to re-establishment of growth of the MV-1-Lu cells.

15

20

As can be seen from Fig. 4, the peptide P12, derived from the sequence of TGF β 1, is the one that exhibits greater inhibitory activity of TGF β 1. For more detailed investigation of the inhibitory effect of peptide P12, an investigation was conducted into the effect of the concentration of the peptide on inhibition of the cytokine, which is described below.

Dose-response test of the inhibition of TGF β 1 by the 10 peptide P12

The effect of the concentration of peptide P12 on inhibition of the activity of TGF β 1 was investigated. As this peptide was not readily soluble in the test medium, stock solutions or suspensions were prepared with a nominal concentration of peptide (that which would have been achieved if the peptide had dissolved completely) and aliquots were taken from these, and were filtered or even were used directly for the inhibition tests.

Fig. 5 examines the inhibitory effect of nominal concentrations of peptide, before and after filtration. It can be seen that peptide P12, with and without filtration, has practically the same activity.

25 Once the results had been obtained with peptide P12, it was decided to lengthen the peptide, both in the N-terminal and the C-terminal direction, and to investigate the effect on its activity. In addition, changes were made to its sequence to improve 30 solubility and study the of importance the two cysteines in its sequence on the inhibitory activity of $TGF\beta 1$. The peptides synthesized are stated in Table 3.

Fig. 6 shows the results of inhibition of $TGF\beta 1$ by the peptides in Table 3.

It can be seen from Fig. 6 that peptide P29 is active. This peptide includes the previously tested peptide P12 and has 9 extra amino acids towards the Nterminal end (Fig. 4). Investigations conducted Quian SW et al. (1992) Proc. Natl. Acad. Sci. 89:6290-10 6294) and by Burmester JK et al. (1993) Proc. Natl. Acad. Sci. 90:8628-8632) using chimeric recombinant proteins identified a region of $TGF\beta1$ that is necessary for the activity of this cytokine (amino acids 40 to 8215 in the sequence of mature $TGF\beta 1)$. It was speculated that peptide P29 (amino acids 34 to 56 in the sequence of mature TGFeta1), extending over a larger region than peptide P12 (amino acids 43 to 56), might acquire a three-dimensional structure more like the structure of the TGF β 1 in circulation. For this reason, peptide P29 20 was used for tests of binding to the cell receptors, based on affinity labelling.

15

Tests of inhibition of the binding of $TGF\beta 1$ to its receptors by peptide P29 (affinity labelling)

Peptide P29, derived from the sequence of TGF β 1, was used in affinity labelling tests for verifying its capacity for inhibition of the binding of TGF β 1 to its cell receptors (Material and Methods).

Owing to the different activity of the batches of $^{125}I-TGF\beta 1$ employed, the concentrations of peptide used in the tests were adjusted according to the concentration of the $^{125}I-TGF\beta 1$ batch used in each case. The results of these tests are shown in Figs. 7 and 8.

Further tests were carried out to find the minimum concentration required for blocking the binding of $^{125}\text{I-TGF}\beta1$ to the cell receptors.

Inhibition of $TGF\beta 1$ by peptides derived from the sequence of the type III receptor of the rat

With the aim of finding new peptides that are inhibitors of the activity of $TGF\beta 1$, peptides derived from the type III receptor of the rat were synthesized. Some peptides were chosen on the basis of regions of their sequence that were predicted as complementary to blocks of amino acids of the sequence of $TGF\beta 1$. It was hoped that these peptides would be capable of binding to free $TGF\beta 1$, sequestering it and preventing its binding to the cell receptors.

Other peptides were synthesized by overlapping 10 amino acids and covering part of the extracellular region of the type III receptor (amino acids 45 to 410). It has been described that a soluble type III receptor exists that corresponds to the extracellular region of the receptor, this region is cut from the membrane and acts as a sequestrator of the TGF\$1 in

circulation (López Casillas F. et al. (1991)67:785-795). studies Later described two possible regions of binding to $TGF\beta1$, one of which is located at the N-terminal end of the receptor (López-Casillas et al. (1994) J. Cell Biol. 124:557-568) and the other is located in the region closest to the membrane, towards the C-terminal end (Fukushima D. et al. (1993) J. Biol. Chem. 268:22710-22715; Pepin MC et al. (1995) FEBS Lett 377:368-372). For these reasons peptides extracellular region of this receptor were synthesized, on the supposition that these peptides might be capable of sequestering the circulating $TGF\beta1$.

The peptides synthesized are shown in Table 4.

15 Table 4. Peptides derived from the type III receptor of the rat. The number of the peptide and its sequence are P39 to P65 are peptides predicted complementary to $TGF\beta1$ and P66 to P138 are overlapping covering the extracellular region 20 receptor. For convenience of synthesis, all the peptides were synthesized with an alanine added at the C-terminal end which is not shown in the table.

15

30

35

The peptides in Table 4 were tested for their capacity to block TGF β 1 in the model of inhibition of the MV-1-Lu cell line. Since TGF β 1 is able to inhibit the growth of this line, inhibition of TGF β 1 by the peptides would be able to re-establish cell growth. These tests are shown in Figs. 9 to 12.

As can be seen in Figs. 9 to 12, there are various peptides that are able to inhibit the growth of the MV-1-Lu cell line to a greater or lesser degree, but only peptide P54 is capable of inhibiting the activity of TGF β 1 almost completely. With the aim of conducting a more thorough investigation of this peptide, tests were carried out using different concentrations of peptide against a fixed concentration of TGF β 1 of 200 pg/ml.

Dose-response test of the inhibition of TGFeta 1 by peptide P54

The effect of the concentration of peptide P54 on inhibition of the activity of TGFβ1 was investigated. In view of the low solubility of this peptide, stock solutions with nominal concentration of peptide were prepared, as was done in the case of peptide P12, and aliquots were taken from them, and filtered, or even used directly for the inhibition tests.

Fig. 13 examines the inhibitory effect of nominal concentrations of peptide, before and after filtration. It can be seen that there is no measurable inhibitory activity in the filtrate of peptide P54.

Having verified the capacity of peptide P54 to inhibit the activity of $TGF\beta 1$ in a manner that depends on the dose used, we proceeded to synthesize new peptides, taking as a basis the sequence of P54, with the aim of trying to improve the solubility and hence its activity at lower doses. Two peptides derived from

the human type III receptor were also synthesized. One of these peptides (P144) is equivalent to peptide P54. The other peptide (P145) is similar to peptide P106 of the type III receptor of the rat, which had also demonstrated activity. These new peptides are shown in Table 5.

PCy 10

The test of activity of the peptides in Table 5 is shown in Fig. 14.

Dose-response test of inhibition of $TGF\beta 1$ by peptide P144

20

25

A dose-response test was carried out with peptide P144 derived from the sequence of the human type III receptor, with the aim of testing whether its activity was dependent on the concentration (Fig. 15). It can be seen that the activity of the peptide decreases with the decrease in the concentration of peptide used in the tests.

15

Tests of inhibition of the binding of $TGF\beta1$ to its receptors by peptide P144 (affinity labelling)

Peptide P144 derived from the sequence of the human type III receptor was used in affinity labelling tests for verifying its ability to inhibit the binding of TGF β 1 to its cell receptors (Material and Methods).

Owing to the different activity of the batches of $^{125}\text{I-TGF}\beta1$ employed, the concentrations of peptide used in the tests were adjusted according to the concentration of the $^{125}\text{I-TGF}\beta1$ batch used in each case. The results of these tests are shown in Fig. 15.

After verifying inhibition of the binding of TGF β 1 to its cell receptors by peptide P144, a new test was conducted with the aim of titrating peptide P144. It was observed that the peptide lost its activity at a concentration of 2×10^5 times the molar concentration of $^{125}\text{I-TGF}\beta$ 1.

Inhibition of TGF β 1 by peptides derived from other proteins with ability to bind to TGF β 1 and predicted as complementary to TGF β 1

The peptides in Table 6, derived from proteins capable of binding to $TGF\beta 1$, were synthesized in this series.

Table 6. Peptides derived from various proteins capable of binding to TGF β 1 (type II receptor P146, fetuin P147 30 to P149, endoglin P150 to P154 and $\alpha 2$ -macroglobulin P155 to P179). The number of the peptide is shown, together with its position in the complete sequence, amino acid sequence, and its origin. 35 convenience of synthesis, all the peptides were

 $^{\rm -}$ 34 $^{\rm -}$ synthesized with an alanine added at the C-terminal end which is not shown in the table.

Figs. 17 and 18 show the inhibitory activity of the peptides derived from Table 10.

As can be seen in Figs. 17 and 18, only peptide P150 showed activity greater than 50%. However, peptides P146 and P149, which had been described as active by Demetriou M et al. (1996) J. Biol. Chem. 271:12755-12761, were not found to be active under the conditions employed for this test.

Measurement by flow cytometry of the inhibitory effect of synthetic peptides on the binding of $TGF\beta1$ to its

Peptides derived from previous syntheses, both those that were synthesized from the sequence of $TGF\beta1$ and those from the type III receptor, were used for measuring, by flow cytometry, their capacity to inhibit the binding of $TGF\beta 1$ to the cell receptors. In these tests the cells are incubated with the peptide before adding TGF\$1-biotin, which will be detected using avidin-FITC (Material and Methods). Then the fluorescence emitted by the avidin-FITC is measured: this will be directly proportional to the quantity of TGF β 1 bound to the cells and inversely proportional to the activity of the peptide. The results obtained with the most relevant peptides are shown in Fig. 19 and Table 7.

INHIBITION IN VIVO OF THE ACTIVITY OF TGF\$1

Peptide P144 derived from the sequence of the human type III receptor, which had proved active in the bioassays of inhibition of growth of the MV-1-Lu cell line, was used in the tests in vivo for studying its inhibitory effect in the induction of experimental cirrhosis with CCl₄, in a rat model.

30

35

Model of experimental cirrhosis in Wistar rats

In this model, hepatic cirrhosis is induced by inhalation of carbon tetrachloride, for 11 weeks, twice per week (López Novoa JM et al. (1976) Patología IX:223-240; Camps J. et al. (1987) Gastroenterology 93:498-505) as described in Material and Methods.

Peptide P144 was administered in accordance with two protocols:

- 10 1. Protocol 1: The peptide was administered on alternate days by the intraperitoneal route during the cirrhosis induction process (11 weeks). Figs. 20 and 21.
- 2. Protocol 2: The peptide was administered on alternate days by the intraperitoneal route for 3 weeks, once cirrhosis was established, i.e. at 12 weeks from the start of induction of cirrhosis. Figs. 22 and 23.

The production of collagen in both protocols was 20 measured by two techniques:

Figs. 36 and 38 show total collagen production measured by staining liver sections (two per animal) with Fast Green and Direct Red, elution of the colour reading in a spectrophotometer (Material Methods) (López de León Α. and Rojkind (1985)Histochem. Cytochem. 33:737-743; Gaudio E. et (1993) Int. J. Exp. Path. 74:463-469).

Figs. 21 and 23 show collagen production, measured by image analysis of liver sections stained with Sirius Red, using light microscopy (Material and Methods).

As can be seen in Fig. 20, significant differences are observed (P < 0.05) between the group of rats treated with peptide P144 (Tto_1) and the control group of cirrhotic rats (Ci_1) on investigating the ratio of collagen to total protein. In Fig. 37, the differences between the group of rats treated with peptide P144 (Tto_1) and the control group of cirrhotic rats (Ci_1) are

25

30

also significant (P < 0.001) when the area of fibrosis is investigated.

As can be seen in Figs. 22 and 23, which show the results for the rats treated once cirrhosis was established, the differences between the groups of rats treated with peptide P144 (Tto_2) and the cirrhotic rats without treatment (Ci_2) are not significant when using either of the two techniques for measuring fibrosis.

The two techniques employed for measuring collagen were compared using linear regression with the aim of verifying the randomness of selection of the fields for investigation in each preparation and hence the validity of the image analysis, Figs. 24 and 25.

As can be seen from Figs. 24 and 25, there is a correlation between the two techniques with R > 0.85 in both cases, which is highly significant (F \leq 0.001). This confirms that acquisition of the images for investigation was effected entirely randomly and hence confirms the validity of the data obtained by image analysis.

Figs. 26 and 27 show the images obtained by light microscopy from liver preparations stained with Sirius Red at a magnification of 10X obtained from livers of rats treated during the cirrhosis induction process (Ci₁ and Tto₁).

The images in Fig. 26 were obtained without employing any type of filter.

Fig. 27 shows the images once they had been modified for investigation using special software. These modifications consist of application of two filters, one of polarized light and the other of green light, for the purpose of improving the quality of the images and facilitating automated examination of them.

Figs. 26 and 27 reveal that there are differences 35 between the images obtained from the cirrhotic rats (Ci_1) and those obtained from the rats treated with peptide P144 (Tto_1) .

30

35

The differences in effectiveness between protocols 1 and 2 might be due to the fact that production of TGF β 1 might be much less once cirrhosis is induced (protocol 2) than during the process of induction of cirrhosis with CCl₄ (protocol 1), and might even be at normal levels, so that the effect of treatment with peptide P144 would be less pronounced in protocol 2 than in protocol 1.

When we compare the groups of untreated cirrhotic 10 rats, the end of the process of induction of cirrhosis (Ci_1) with the untreated cirrhotic rats at 4 weeks from the end of induction (Ci_2) , we find that there are significant differences (P = 0.016) between the two groups (Fig. 28), which would indicate that 15 there is partial regression of cirrhosis when the cirrhotizing agent is removed, an observation that has been published by various authors (Szende-B et (1992)In Vivo 6:355-361; Columbano Α (1996)Carcinogenesis 17:395-400).

These differences in effectiveness between the two protocols might also be due to the protocol itself, since the animals of protocol 2 are only treated for 3 weeks on alternate days, whereas the animals of protocol 1 are treated for a longer period of time (7 weeks, also on alternate days).

The results obtained demonstrate that it is possible to inhibit $TGF\beta 1$ both in vitro and in vivo by means of synthetic peptides derived from different proteins. In future it would be of great interest to to increase the biological activity of peptides. This might be accomplished by systematically replacing each of the amino acids of their sequences by the other 19. Once the peptide with greater activity was achieved it would be necessary to prepare mimotopes (McConnell-SJ (1994) Gene 151:115-118; Steward-MW (1995) J. Virol. 69:7668-7673) thereof with the aim of

increasing the average life of the inhibitory agent in the organism.

DESCRIPTION OF THE FIGURES

5

10

20

- Fig. 1. Inhibition of binding of TGF β 1 to the MV-1-Lu cells by peptide P144, measured by flow cytometry. A, image obtained on examining the cells incubated with biotinylated TGF\$1 and developed with avidin-FITC. B, image obtained on examining the cells incubated with avidin-FITC without prior addition of TGF β 1. C, image obtained on examining the cells incubated with $TGF\beta 1$ previously incubated with peptide P144 concentration of 0.42 $\mu g/\mu l$, and developed with avidin-FITC. The fluorescence emitted is shown abscissa, while the ordinate shows the number of cells for each value of fluorescence. The fields corresponding to the cells labelled with TGF\$1-biotin and avidin-FITC (M2) and to the unlabelled cells (M1) are also shown.
- 2. Schematic representation of the process of cirrhosis by CCl4. Black arrows indicate when two weekly doses of CCl4 were administered to the rats, and black 25 dashed arrows show when there was one weekly dose. The grey arrows indicate administration of peptide P144. A: Healthy controls; B: Healthy controls + P144, B1: with peptide 70 $\mu g/day$; C: Cirrhotic; C₁ with saline; C₂ with 70 μg/day; D: Cirrhotic with 30 phenobarbital; D_1 plus saline; D_2 plus peptide 70 μg/day.
 - Fig. 3. Effect of TGF β 1 on growth of MV-1-Lu cells. The cells are cultivated at a density of 5000 cells/well at

the concentrations of TGF β 1 indicated, pg/ml. Abscissa: TGF β 1 concentration (pg/ml); Ordinate: c.p.m.

- Fig. 4. Percentage inhibition of TGF β 1 (200 pg/ml) by peptides from TGF β 1. All the peptides were tested at a concentration of 200 μ g/ml. Inhibition of TGF β 1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGF β 1.
- Fig. 5. Percentage inhibition of the activity of TGF β 1 (200 pg/ml) in the presence of various nominal concentrations of peptide P12, filtered (\spadesuit) and unfiltered (\bullet).
- Fig. 6. Percentage inhibition of TGF β 1 (200 pg/ml) by peptides from TGF β 1. All the peptides were tested at a concentration of 200 μ g/ml. Inhibition of TGF β 1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGF β 1.

Fig. 7. Autoradiograph of an affinity labelling test of the receptors of $TGF\beta1$. Lane C1: effect of incubation of the cells with a concentration of 0.16 μM of $^{125}I-TGF\beta 1$ which corresponds to an activity of 0.3 μCi (positive control). Lane C2: effect of preincubation of the cells 25 with a concentration of non-radioactive $TGF\beta1$ 10 times greater than that of $^{125}\text{I-TGF}\beta1$ (negative control). Lane C3: preincubation was effected with peptide P29 at a 10^6 times concentration greater than the concentration of $^{125}\mbox{I-TGF}\beta\mbox{1.}$ It can be seen that there 30 is inhibition of the binding of $^{125}\text{I-TGF}\beta1$ to the type I, II and III cell receptors both by peptide P29 and by non-radioactive TGFβ1.

- Fig. 8. Autoradiograph of an affinity labelling test of the receptors of $TGF\beta1$. Lanes C1 to C6: effect of preincubation of the MV-1-Lu cells, with different concentrations of peptide P29 (10^6 , 8×10^5 , 6×10^5 , 4×10^5 , $2 \text{x} 10^5$ and 10^5 times the molar concentration of $^{125}\text{I-TGF}\beta 1$ 5 respectively), prior to addition of ¹²⁵I-TGFβ1. Lane C7: effect of preincubation of the MV-1-Lu cells with unlabelled TGF β 1 (10 2 times the molar concentration of $^{125}\text{I-TGF}\beta1)$ prior to addition of $^{125}\text{I-TGF}\beta1$ (negative 10 control). Lane C8: effect of incubation of the MV-1-Lu cells with a concentration of 0.42 μ M of $^{125}I-TGF\beta1$, corresponding to an activity of 0.4 μ Ci, without prior preincubation (positive control).
- Fig. 9. Percentage inhibition of TGF β 1 (200 pg/ml) by receptor peptides predicted as complementary to regions of TGF β 1. All the peptides were tested at a concentration of 200 μ g/ml. Inhibition of TGF β 1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGF β 1.
- Fig. 10. Percentage inhibition of TGF β 1 (200 pg/ml) by overlapping peptides derived from the extracellular region of the type III receptor. All the peptides were tested at a concentration of 200 μ g/ml. Inhibition of TGF β 1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGF β 1.
- Fig. 11. Percentage inhibition of TGF β 1 (200 pg/ml) by overlapping peptides derived from the extracellular region of the type III receptor. All the peptides were tested at a concentration of 200 μ g/ml. Inhibition of TGF β 1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGF β 1.

Fig. 12. Percentage inhibition of TGF β 1 (200 pg/ml) by overlapping peptides derived from the extracellular region of the type III receptor. All the peptides were tested at a concentration of 200 μ g/ml. Inhibition of TGF β 1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGF β 1.

Fig. 13. Percentage inhibition of the activity of TGFβ1 (200 pg/ml) in the presence of different nominal concentrations of peptide P54, filtered (♦) and unfiltered (•).

Fig. 14. Percentage inhibition of TGFβ1 (200 pg/ml) by receptor peptides derived from modification of peptide P54 (P139 to P143) and of the peptides derived from the human type III receptor (P144 and P145). All the peptides were tested at a concentration of 200 μg/ml. Inhibition of TGFβ1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGFβ1.

20

Fig. 15. Percentage inhibition of the activity of $TGF\beta1$ (200 pg/ml) in the presence of different nominal concentrations of peptide P144 without filtration.

Fig. 16. Autoradiograph of an affinity labelling test of the receptors of TGFβ1. Lane C1: preincubation was effected with peptide P144 at a concentration 10⁶ times greater than the molar concentration of ¹²⁵I-TGFβ1. Lanes C2 and C3: effect of preincubation of the cells with a concentration of non-radioactive TGFβ1 10 times greater than that of ¹²⁵I-TGFβ1 (negative control). Lanes C4 and C5: effect of incubation of the cells with a concentration of 0.1 μM of ¹²⁵I-TGFβ1 that corresponds to an activity of 0.2 μCi (positive control). It can be seen that there is inhibition of the binding of ¹²⁵I-TGFβ1

to the cell receptors both by peptide P144 and by the non-radioactive $TGF\beta 1$.

Fig. 17. Percentage inhibition of TGF β 1 (200 pg/ml) by peptides derived from human type II receptor (P146), from fetuin (P147 to P149) and from endoglin (P150 to P154). All the peptides were tested at a concentration of 200 μ g/ml. Inhibition of TGF β 1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGF β 1.

- Fig. 18. Percentage inhibition of TGF β 1 (200 pg/ml) by peptides derived from α 2-macroglobulin. All the peptides were tested at a concentration of 200 μ g/ml. Inhibition of TGF β 1 of 100% corresponds to the growth of MV-1-Lu cells that is obtained in the absence of TGF β 1.
- Fig. 19. Percentage inhibition of the binding of TGFβ1 to MV-1-Lu cells by various synthetic peptides.
 20 Inhibition was investigated by measuring the percentage of labelled cells (emit fluorescence) and unlabelled cells (do not emit fluorescence) for each peptide (Material and Methods).
- Fig. 20. Effect of administration of peptide P144 on 25 collagen synthesis during experimental cirrhosis induction with CCl4. The ratio of collagen to total protein is shown on the ordinate. The abscissa shows the various groups of rats: Co= healthy rats; Co+P144= 30 healthy rats treated with peptide P144; $Tto_1 = rats$ subjected to induction of cirrhosis with CCl₄ administered peptide P144 on alternate days during this period and Ci_1 = rats subjected to induction of cirrhosis with CCl_4 for 11 weeks and not treated with peptide 35 P144.

Fig. 21. Effect of administration of peptide P144 on collagen synthesis during experimental cirrhosis induction with CCl4. The ordinate shows the ratio of the of fibrosis area to the total in tissue preparations stained with Sirius Red. The abscissa shows the various groups of rats: Co= healthy rats; Co+P144= healthy rats treated with the peptide; Tto_1 = rats subjected to induction of cirrhosis with CCl4 and administered peptide P144 on alternate days during this period and Ci1= rats subjected to induction of cirrhosis with CCl₄ for 11 weeks and not treated with peptide P144.

Fig. 22. Effect of administration of peptide P144 on collagen synthesis once cirrhosis has been induced with CCl₄. The ordinate shows the ratio of collagen to total protein. The abscissa shows the various groups of rats: Co= healthy rats; Co+P144= healthy rats treated with the peptide; Tto₂= rats subjected to induction of cirrhosis with CCl₄ and administered peptide P144 on alternate days at the end of this period and Ci₂= rats subjected to induction of cirrhosis with CCl₄ for 11 weeks and not treated with peptide P144.
